Abstract

There is a tremendous unmet need to discover more potent and safe drugs for the treatment of Alzheimer's disease (AD). Reduced cholinergic activity and oxidative stress have been recognized as a major contributing factor in the pathogenesis of AD. Therefore, inhibition of cholinesterase and oxidation are the two promising strategies in the development of a drug for AD. This study determined the anti-acetylcholinesterase (AChE) activity, anti-butyrylcholinesterase (BChE) activity, DPPH free radical scavenging and antioxidant properties of Glycomis pentaphylla (Rutaceae). The objective of this study is to measure G. pentaphylla anti-AChE, anti-BChE, DPPH free radical scavenging, lipid peroxidation inhibition, antibacterial potentials to find out the MIC (minimum inhibitory concentration) against different pathogenic bacteria. G. pentaphylla leaf extract (GPEx) is exploited in the presented research to estimate its anticholinesterase, antioxidant potentials, and antibacterial properties. The cholinesterase inhibitory properties was quantified by modified Ellman method, and antioxidant potentials were evaluated by the assay of radical scavenging, and inhibition of lipid peroxidation. The antibacterial activity and minimum inhibitory concentration (MIC) were determined using agar well diffusion method. The methanolic extract exhibited significant dual acetycholinesterase (AChE) and butyryl cholinesterase (BChE) effect. The IC50 values of AChE and BChE were 325.1±0.91, and 42.1±3.31 μg/ml. Furthermore, the extract showed radical scavenging ability, and lipid peroxidation inhibitory effect. The IC50 values of the extract for DPPH and hydroxyl free radical scavenging, and lipid peroxidation inhibition assay were 95.6±0.68, 198.0±1.39, and 288.7±0.91 μg/ml, respectively. Phytochemical screening of the extract revealed the presence of significant total phenolics and flavonoids contents. Additionally, the extract showed good effect with the zone of inhibition ranging 12–16 mm in diameter against Salmonella typhi, Pseudomonas aeruginosa, Staphylococcus aureus. The tested sample reflects potential antioxidant and anticholinesterase inhibitory potentiality which may warrant its effectiveness in the treatment of AD along with good antibacterial properties.

Keywords: Alzheimer’s disease; Glycomis pentaphylla; anticholinesterase; anti-oxidant; antibacterial; radical scavenging; lipid peroxidation.

1. INTRODUCTION

Alzheimer’s disease (AD) is a progressive neurodegenerative disorder characterized by gradual memory loss, cognitive deficit and behavioural aberration, and the most predominant cause of dementia in the elderly having age more than 65 years[1–3]. It has been estimated that around 35 million people are now afflicted by the AD, and currently it is the fourth leading cause of death in the elderly person [3,4] and it is inferred that it may be reached to 65.7 million by 2030 [2].
Many factors are hypothesized to be involved in the pathophysiology of the AD such as oxidative stress, deposition of senile plaques, the formation of neurofibrillary tangles of the microtubule-associated protein tau, and profound deficits in cholinergic transmission is to be the hallmarks of neuropathophysiology of AD [2,5–8]. Understanding the etiology and pathogenesis of AD has been progressed, effective drugs remain limited yet. Reduced cholinergic activity and oxidative stress have been recognized as a major contributing factor in the pathogenesis of AD [2,9]. The deficit of cholinergic neurons and the associated decrease in levels of acetylcholine (ACh) has been found to correlate well with the cognitive impairment seen in AD patients [10].

The cognitive impairment observed in the AD is correlated with the loss of cholinergic neurons and its associated acetylcholine reduction [2,10]. The undue breakdown of acetylcholine by the increased activity of acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) is implicated in the progression of the AD. Thus, inhibition of these two enzymes are the main strategy followed for AD and currently majority of drugs such as tacrine, donepezil, rivastigmine and galantamine are available for AD treatment are cholinesterase inhibitors (ChEI) despite it is only used for mild to moderate AD and could not reverse the disease progression simply they improve the symptoms [7,11,12]. In addition, these available drugs have adverse effects such as hepatotoxicity and gastrointestinal disturbances [13]. Therefore, in recent years much attention has been drawing to develop safe, cost-effective and active anti-cholinesterase from natural sources.

It has been reported that the reactive oxygen species (ROS) and other free radicals generated from activated neutrophils and macrophages during oxidative stress play an important role in the pathogenesis of AD [14]. A number of studies indicated that oxidative stress and Aβ protein are linked each other because Aβ induces oxidative stress in vivo and in vitro [15,16] and oxidative stress increases the production of Aβ [17,18]. Therefore, antioxidant therapy has been suggested to be successful in improving cognitive function and behavioural deficits in patients with mild to moderate AD [19]. Natural products are the important source of antioxidants which can be beneficial for AD therapy.

The emergence of multi-drug resistance pathogenic bacterial strains is a major medical concern globally and these antibiotics have an adverse reaction such as hypersensitivity, immune-suppression and allergic reactions lead to a search for new and active antibacterial compounds to combat infections against these pathogenic bacteria [19–21]. Therefore, plants or natural products would be an enormous resource to discover new compounds or drug-like molecule which will be helpful for antibiotic discovery and development.

The G. pentaphylla (Orange berry) is an evergreen shrub and it grows usually 4m tall and widely distributed throughout the world including various parts of Bangladesh [22]. It is widely distributed in Bangladesh, India Malaysia and Southern China to the Philippine Islands but this plant is native to eastern, southern, and southeastern Asia and north-eastern Australia [23]. Traditionally, this plant is used to reduce fever, liver complications, various intestinal parasites [23], and toothache and bleeding [22], all forms of cancers, hepatic disorder, rheumatic fever [24]. This traditional use should be supported by the scientific evaluations. In addition, it is reported that G. pentaphylla possessed anti-hepatocellular carcinoma activity, hepatoprotective activity, and antibacterial activity [23].

Therefore, the present study was carried out with an aim to explore the cholinesterase (AChE and BChE) inhibitory activity and antioxidant properties of G. pentaphylla as well as antibacterial activity with particular emphasis in order to treat AD.

2. MATERIALS AND METHODS

2.1 Plant material

The plant leaves of G. pentaphylla were collected from the Islamic University premises, Kushtia, Bangladesh in February 2017 by the authors and collected plant sample was identified by an expert taxonomist. A voucher specimen has been deposited at the Department of Biotechnology and Genetic Engineering, Islamic University, Kushtia, Bangladesh. The freshly collected plants were
cleaned to remove dust.

2.2 Extraction of plant material

The leaves of *G. pentaphylla* plant were air dried and ground. The powdered plant (500 g) was subjected to extraction with methanol at room temperature for 7 days with sporadic shaking. The extractive solution was filtered and concentrated under vacuum in a rotary evaporator at 45 °C to yield 17 g of the crude extract (GPEx).

2.3 Enzyme sources

Adult Long-Evans rat (125-150g) brain homogenate was used as the source of acetylcholinesterase enzyme and human blood was used as the source of butyrylcholinesterase enzyme. The rats were purchased from the animal research branch of the International Centre for Diarrhoeal Disease and Research, Bangladesh (ICDDR, B). The approval for this study was taken from the Department of Biotechnology and Genetic Engineering, Islamic University, Kushtia, Bangladesh.

2.4 Chemicals

The chemicals used in this study were analytical grade. DPPH (2, 2′-diphenyl-1-picrylhydrazyl), aluminum chloride, potassium ferricyanide, ascorbic acid, Folinciocalteu reagent, Tris–HCl and triton X-100 were obtained from Sigma-Aldrich (India). Gallic acid was obtained from Wako Pure Chemical Company Ltd., Japan. 5,5′-dithio-bis-(2-nitro) benzoic acid (DTNB), acetylthiocholine iodide (ATCI), S-butyrylthiocholine, galantamine, and donepezil were obtained from Sigma-Aldrich, Japan. Unless otherwise specified, all other chemicals were of analytical grade.

2.5 Determination of total phenolic content

The concentration of total phenolics of GPEx was determined by the method Folin-Ciocalteu [25]. Briefly, a 0.5 ml of plant extract was mixed to 2.5 ml of Folin-Ciocalteu reagent which was diluted 10 times with water and 2.5 ml of sodium carbonate (7.5%) solution and the reaction mixture was allowed to incubate for 20 min at room temperature (25°C) to complete the reaction thereafter the absorbance of the reaction mixture was measured at 760 nm by spectrophotometer. To quantify the total phenolics, the Gallic acid standard curve was exploited and the results were represented as mg of Gallic acid equivalent (GAE)/g of dried extract.

2.6 Determination of total flavonoid content

The aluminium chloride colourimetric method with slight modification was employed to determine the total flavonoid content of GPEx [26]. In short, 1.0 ml of each concentration of crude extract of GPEx was added with 3.0 ml of methanol, 0.2 ml of 10% AlCl3, 0.2 ml of 1 M potassium acetate and 5.6 ml of distilled water was added to the resulting mixture which was then incubated at room temperature for 30 min to complete the reaction. At 420 nm, the absorbance was recorded of the reaction mixture by spectrophotometer. Gallic acid was used as standard and the results were expressed as milligrams of gallic acid equivalents per gram of dried fraction [2].

2.7 Determination of DPPH radical scavenging activity

DPPH assay was used to assess the free radical scavenging activity of the extract according to the method described by Choi et al. with slight modifications [27]. Briefly, 3 ml of a methanol solution of DPPH and 2 ml of a methanol solution of plant extract or reference standard catechin at various concentrations was mixed into the test tube and allowed to incubate at room temperature (25°C) for 30 min in dark place to complete the reaction. The absorbance of the solution was measured out by spectrophotometer at 517 nm. DPPH free radical scavenging ability (%) was calculated by using the formula:

\[
\frac{[An \text{ absorbance of control } - \text{ An absorbance of sample}]}{An \text{ absorbance of control}} \times 100
\]

2.8 Determination of hydroxyl radical scavenging activity
The hydroxyl free radical scavenging activity of the methanol crude extract of GPEx was determined by the method as described by Elizabeth and Rao with a slight modification [28]. At various concentrations the plant extract or reference compound was mixed with a reaction mixture contained, in a final volume of 1 ml: 2-deoxy-2-ribose (2.8 mM); KH2PO4- KOH buffer (20 mM, pH 7.4); FeCl3 (100 μM); EDTA (100 μM); H2O2 (1.0 mM); and catechin (100 μM). The mixture was then incubated for 1 h at 37 °C and 0.5 ml of the reaction mixture was heated at 90 °C for 15 min after addition of 1 ml of 2.8 % TCA and 1 ml of 1 % aqueous TBA to develop the colour. After cooling, the absorbance was measured at 532 nm against an appropriate blank solution [2]. Hydroxyl radical scavenging ability (%) was calculated by using the formula:

\[
\left(\frac{\text{An absorbance of control} - \text{An absorbance of sample}}{\text{An absorbance of control}}\right) \times 100
\]

2.9 Determination of cholinesterase (ChE) inhibitory activities

The acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) inhibitory assay were performed according to the colourimetric Ellman method with slight modification [2,29]. For the AChE enzyme source, rat brain was homogenized in a homogenizer with 5 volumes of a homogenization buffer [10 mM Tris–HCl (pH 7.2), which contained 1 M NaCl, 50 mM MgCl2 and 1 % Triton X-100], and centrifuged at 10,000 g for 30 min. The resulting supernatant was used as an enzyme source. For the BChE enzyme source, human blood from anonymous healthy men subject was provided by the Islamic University Medical Center, Kushtia, Bangladesh and collected in EDTA treated (1 mg/ml) glass tubes. The tubes were centrifuged at 2000 g for 10 min to eliminate the red blood cells. The resulting plasma (supernatant) was then recuperated, diluted (1/200) with 50mM phosphate buffer (pH 7.4) and was used immediately for studying butyrylcholinesterase activity. The rates of hydrolysis by acetylcholinesterase were monitored spectrophotometrically. Each extract or standard (500 μl) was mixed with an enzyme solution (200 μl) and incubated at 37 °C for 15 min. Absorbance at 405 nm was read immediately after adding an Ellman’s reaction mixture [3.5 ml; 0.5 mM acetylthiocholine iodide (ATCI), 1 mM DTNB in a 50 mM sodium phosphate buffer (pH 8.0)] with the incubated reaction mixture. The hydrolysis of ATCI was monitored by the formation of yellow 5-thio-2-nitrobenzoate anion as a result of the reaction of DTNB with thiocholine. Reading was repeated for 10 min at 2 min intervals to verify that the reaction occurred linearly. The blank reaction was measured by substituting saline for the enzyme. Percentage of inhibition of AChE/BChE was determined by comparison of rates of reaction of samples relative to blank sample using the formula

\[
\frac{(E-S)}{E} \times 100
\]

where E is the activity of enzyme without test sample and S is the activity of the enzyme with the test sample. The experiments were done in triplicates. Donepezil (anticholinesterase drug) was used as a standard. Assessment of BChE inhibition was performed as described above except that the enzyme solution was 50 μl and acetylthiocholine iodide was replaced by butyrylthiocholine iodide. Galantamine was used as positive control. The percentage inhibition of butyrylcholinesterase activity was calculated using the same formula as mentioned above for acetylcholinesterase activity.

2.9 Antibacterial Susceptibility Test and Minimum Inhibitory Concentration (MIC) Determination Test

To assess the antibacterial potentials of the crude methanol extract of GPEx, in vitro antibacterial susceptibility test was performed by agar well diffusion technique [30]. Human pathogenic bacterial culture (0.1%) was swabbed uniformly over the surface of solid nutrient agar media using sterile cotton swab under asceptic condition. After complete drying of the media, 4 mm small bore is filled with the crude extracts at the different concentration (0.5-10 mg/ml) with appropriate control, the inoculated plates were allowed for 24 h incubation. Finally, inhibition zones formed around the well were measured using a calibrated scale within millimeter. All the tests for antibacterial activity were carried out in triplicate.

The methanol crude GPEx extracts were subjected to serial dilution technique (0.5-10mg/ml) to prepare various concentrations for the determination of MIC. The various diluted extracts were applied to wells posed in the nutrient agar media containing inoculums and incubated for 24 h. After
overnight incubation, the growth of the test organisms was observed to determine the MIC.

2.10 Statistical analysis

The data were analyzed by one-way ANOVA followed by Tukey’s test to estimate significant differences between the test and control groups, and IC50 was determined with GraphPad Prism Data Editor for Windows, Version 5.0 (GraphPad Software Inc., San Diego, CA). Values were expressed as a mean ± Standard error of the mean (± SEM). *p<0.05 were considered as statistically significant.

3. RESULTS

3.1 Antioxidant activity

3.1.1 Total phenolics and flavonoid contents of G. pentaphylla

This research aims to evaluate the antioxidative and anticholinergic effects of the GPEx. For assessing the antioxidative effects, total phenolic and flavonoid contents of GPEx, DPPH radical scavenging capacity, hydroxyl radical scavenging effect and lipid peroxidation inhibitory effects were screened. Total phenolic and flavonoid contents were calculated using the standard curve for Gallic acid. Phenolic compounds have been reported to show anti-Aβ (amyloid β protein) aggregation effects in AD indicating the pivotal role of phenolics in preventing the Alzheimer’s progression [2,10,31]. Flavonoids are known to serve as potential antioxidants for their radical scavenging, an ion chelating and lipid peroxidation inhibiting properties [10,32] preventing or slowing the progression of the AD by interfering the generation of amyloid-β peptides and its polymerization into neurotoxic oligomeric aggregates thereby reducing aggregation of tau proteins [31]. Higher content of total phenolic (28.23 mg of GAE/g of dried extract) and flavonoid (181.76 mg of GAE/g of dried extract) in TGEx, therefore, may carry an immense importance to evaluate its role in controlling AD.

3.1.2 DPPH radical scavenging activity of G. pentaphylla

Radical scavenging activity is very important to prevent the deleterious role of free radicals in AD [2,33]. DPPH is a stable free radical contains an odd electron and DPPH antioxidant assay is based on the ability of DPPH to decolourize in the presence of antioxidants. Decolorization of DPPH after accepting an electron donated by an antioxidant compound is quantitatively measured by the change in absorbance and % of scavenging activity. DPPH radical scavenging assay for G. pentaphylla is shown in Figure 1(A). The results of this study showed very significant DPPH scavenging activity with an IC50 value of 95.6±0.68 μg/ml and found to be comparable with that of the standard antioxidative agent ascorbic acid showing IC50 value 1.97±0.27μg/ml.

3.1.3 Hydroxyl radical scavenging activity

Hydroxyl radicals are the major reactive oxygen species that severely damage the neurons in AD [34]. In the hydroxyl radical scavenging activity, the ability of GPEx to remove the formed hydroxyl radical in solution was evaluated quantitatively by Fenton-reaction initiated deoxyribose degradation assay and the result has been shown in Figure 1(B).

The test sample significantly scavenged the hydroxyl radicals generated in the reaction in a dose-dependent manner with an IC50 value of 198.0±1.39 µg/ml which was significant compared to that (25.44±0.63 µg/ml) of the reference standard (+)-catechin. Removal of hydroxyl radicals from the reaction mixture decolourized the pink chromogen which was quantitatively measured by the change in absorbance at 532 nm. The results demonstrate very promising hydroxyl radical scavenging potentials for therapeutic uses. because the cut-off value for antioxidative compounds is 1000 µg/ml [35].
3.1.4 Lipid Peroxidation inhibition activity of G. pentaphylla

Reactive oxygen species produced by ultraviolet light, ionizing radiation, chemical reactions, and metabolic processes have numerous pathological effects, such as causing lipid peroxidation, protein peroxidation, DNA damage, and cellular degeneration related to a variety of diseases including Alzheimer’s disease [36–38]. In the lipid peroxidation inhibition activity, the activity of GPEx against non-enzymatic lipid peroxidation in rat brain homogenate was evaluated. Addition of Fe2+-ascorbate to the brain homogenate caused an increase in lipid peroxidation which was quantitatively measured by the change in absorbance at 532 nm and % of inhibition activity of different concentrations were shown in Figure 2. The GPEx showed that the inhibition of lipid peroxidation was correlated with the increasing concentration of the extract. The IC50 values of the methanol extract and the reference standard (+)-catechin were 288.7±0.91 and 19.50±0.56 μg/ml, respectively.

3.2 Cholinesterase inhibitory activity

3.2.1 AChE inhibitory activity of G. pentaphylla

The inhibitory activity of GPEx against rat brain AChE was determined by widely accepted modified Ellman’s method [29] which estimates the level of AChE using acetylthiocholine iodide (substrate) and DTNB. The inhibitory activity of GPEx was increased with the increasing concentration and showed for 50, 100 and 200 μg/ml concentration of GPEx provided 14.63±0.026 %, 30.4±0.026, and 52.92±0.02 % AChE inhibition respectively, and the IC50 was 325.1±0.91 μg/ml (Figure 3(A)). This concentration-dependent inhibition of GPEx was significant (p < 0.05) compared to control but the IC50 values were higher than that (IC50 = 85.13±0.57) of the reference drug donepezil (Table1).

3.2.2 BChE inhibitory activity of G. pentaphylla

All the cholinesterase inhibitors currently licensed for the AD, inhibit AChE and, to a varying extent, BChE [11,39]. This research has studied the inhibitory actions of GPEx against BChE using the similar methods used for AChE. Similar to AChE inhibitory activity, the GPEx also had very good inhibitory actions against BChE, 11.6+0.35, 20.83+0.05, and 45.61+0.08 % BChE inhibition respectively (Figure 3(B)) with an IC50 value of 42.14±3.31μg/ml whereas galantamine showed the IC50 value of 11.37±0.56 μg/ml (Table1).

Our results demonstrate a dual activity of G. pentaphylla. However, methanol extract showed higher activity against BChE compared with AChE.

3.3 Minimum Inhibitory Concentrations (MIC)

A total of five bacterial species were examined for antibacterial screening with methanolic extract of GPEx. It has been observed that the extract under study only effective against Salmonella typhi, Pseudomonas aeruginosa, Staphylococcus aureus with the zone of inhibition ranges from 12-14 mm, 12-16mm, and 12-15mm in diameter respectively, and found ineffective against Escherichia coli. The findings are summarized in Table 2.

The highest MIC of G. pentaphylla was found against Salmonella typhi, Pseudomonas aeruginosa, Staphylococcus aureus with 500 microgram (5mg/ml).

4. DISCUSSION

AD is the degenerative neuro disorder and prime cause of death in elderly persons, and oxidative imbalance, cholinergic dysfunction is considered to be the major causative factors in the pathogenesis of AD [5,6,8]. Thus, a drug candidate that would inhibit the oxidative stress and cholinergic dysfunction would be useful for the drug development and treatment of AD. The search for new drug molecules with increased effectiveness, safety and lesser adverse effect for neuro-protection would be feasible and possible from the natural sources such as plant extracts and plant-originated compounds; for instance, plant natural alkaloid galantamine was first discovered from
Galanthus sp., which has been approved by FDA in 2001 for treatment of AD.

G. pentaphylla has been reported to possess anti-hepatocellular carcinoma activity, hepatoprotective activity, antibacterial activity [23]. Our findings indicate that G. pentaphylla also possesses acetylcholinesterase and butyrylcholinesterase inhibitory properties with antioxidative activities. In AD patient the cholinergic neurotransmitter is reduced, the acetyl choline breakdown prevention through the inhibition of AChE activity, and increased concentration of acetylcholine enhances the communication between the nerve cells will give a therapeutic benefit in a patient with AD [3]. It has been revealed in our study that the methanol crude extract demonstrated inhibitory activity against both the cholinesterases, AChE and BChE. The IC50 value of this extract were found 325.1±0.91 μg/ml, 42.14±3.31 μg/ml respectively, indicating that methanolic extract has higher specificity for BChE. Dual inhibition of AChE and BChE might more improve the signs and symptoms of AD. However, our results demonstrated the dual anticholinesterase activity of G. pentaphylla.

The brain consumes a lot of oxygen and contains easily oxidizable fatty acids as well as the low amount of antioxidants, therefore, more susceptible to free radical attacks [40]. Several assays such as DPPH, hydroxyl radical scavenging activity, and lipid peroxidation assay were employed to evaluate the antioxidant potentials of G. pentaphylla because a single assay is insufficient to reflect the antioxidant property of a compound. The stable DPPH radical is a widely used method to evaluate the free radical scavenging ability of various samples [1,41]. The DPPH radical scavenging ability of the G. pentaphylla extracts revealed that scavenged DPPH radicals significantly in a dose dependent manner (Fig. 1).

Aβ protein, main hallmark of AD, triggers the generation of free radicals, which leads to the oxidation of protein, lipid and DNA [16,42]. Hydroxyl radicals (OH•) are the major reactive oxygen species that severely damage the neurons in AD. The hydroxyl radical scavenging abilities of the extracts of the plant are presented in Fig. 2. Results revealed that the methanol extract has potential hydroxyl radical scavenging activity with an IC50 of 198.0±1.39 μg/ml, which appeared to higher to that of the reference standard catechin whose IC50 was found to be 25.44±0.63 μg/ml under the same condition.

The ChE inhibitory property and antioxidant activity of G. pentaphylla were supported by the presence of endogeneous polyphenols and flavonoids. Polyphenols are the most abundant antioxidants in the plant kingdom. Recent studies have shown that polyphenols are able to cross the blood-brain barrier [43,44] and play role in neuroprotection [45]. The polyphenolic compound is believed to scavenge free radicals and activate antioxidant enzymes [46] and the antioxidant activity of phenolics has been attributed from their redox properties [47]. Flavonoids are the secondary metabolites of plant and have good antioxidant and neuroprotective potentials [48]. Our results indicate that this extract derived from G. pentaphylla is a noteworthy source of phenolics and flavonoids which may contribute to the inhibition of AChE, BChE and oxidative activities.

The zone of inhibition observed of GPEx against Salmonella typhi, Pseudomonas aeruginosa, Staphylococcus aureus were in the range of 12-16 mm against, while the two strain E. coli and E. coli 14 were found not affected by the extract. It was found at the antibacterial activity of the extracts correlated strongly with the DPPH activity due to the availability of the antioxidant compounds to exert different inhibitory effect against tested organisms [49]. The well-diffusion technique is useful for the qualitative antibacterial screening and it is also important for the quantitative minimum inhibitory concentration (MIC) determination. The MIC is referred to as a gold standard for determining the susceptibility of organisms against antimicrobial [50]. A lower MIC indicates the necessity of less amount of that compound/drug to inhibit the growth of the microorganisms.

5. CONCLUSION

The results obtained from this study clearly indicated that the methanol extract of G. pentaphylla, possibly due to its polyphenolic compounds, displayed a combination of cholinesterase inhibitory activities as well as antioxidant properties and thus may be useful for an effective and safe treatment for Alzheimer’s disease. Besides, it showed promising antibacterial activity. This study provides a
basis to the claim traditional use for the treatment of nervous system disorders including the AD and infectious disease. Thus, the results of presented work support the traditional use of *G. pentaphylla*.

**ACKNOWLEDGEMENT**

We are grateful to the Department of Biotechnology and Genetic Engineering, Islamic University, Bangladesh for providing facilities of this research work.

**Authors’ Contributions**

MRR, TI, and HMF conceived and designed the experiments; MRR, TI, SA, and MAH carried out the anticholinesterase and antioxidant tests. MRR, TI, HMF conducted the antibacterial assay experiments; MRR wrote the manuscript; MRR, and TI performed statistical analysis. All authors read and approved the final manuscript.

**Competing interest**

The authors declare that they have no conflict of interest.

**Funding**

The authors received no direct funding for this research.
